Conflicts of Interest

I have no conflicts of interest to declare related to this presentation.

The distribution of human adipose tissue

Whole body adipose tissue is generally classified as follows:

- Subcutaneous adipose tissue (>80%)
- **Visceral adipose tissue** (in men: <20%; in women: <10%)

*Most ectopic fat is visceral fat.

Lipid overflow results in the ectopic deposition of adipose tissue

Obesity is a Multisystem Disease Associated With Metabolic Complications

Future Indications for weight loss
medications:

- Weight loss
- Weight induced illness
 - N=18

Visceral fat accumulation is strongly associated with weight-related metabolic diseases

To explore the relationship between visceral fat and obesity-related metabolic diseases, a cross-sectional study involved 3,371 participants from Beijing was conducted. Anthropometric measurements and metabolic indicators were assessed, and visceral fat area (VFA) was calculated from non-contrast abdominal computed tomography scans.

Relationship between fat area and number of metabolic diseases

Relationship between fat area and number of metabolic diseases

BMI alone is not enough. The diagnosis of overweight and obesity may require additional anthropometric assessments

Condition	Criteria for people with non-Asian background	Criteria for people with Asian background*
Excess adiposity	BMI ≥ 25 kg/m ²	BMI ≥ 23 kg/m ²
Overweighty	BMI 25–29.9 kg/m ² with WHtR < 0.5 or BMI 25–29.9 kg/m ² with WC < 88 cm in women; BMI 25–29.9 kg/m ² with WC < 102 cm in men	BMI 23–27.4 kg/m ² with WHtR < 0.5 or BMI 23–27.4 kg/m ² with WC < 80 cm in women; BMI 23–27.4 kg/m ² with WC < 90 cm in men
Obesity	BMI ≥ 30 kg/m ² or BMI 25–29.9 kg/m ² with WHtR ≥ 0.5 or BMI 25–29.9 kg/m ² with WC ≥ 88 cm in women; BMI 25–29.9 kg/m ² with WC ≥ 102 cm in men	BMI ≥ 27.5 kg/m ² or BMI 23–27.4 kg/m ² with WHtR ≥ 0.5 or BMI 23–27.4 kg/m ² with WC ≥ 80 cm in women; BMI 23–27.4 kg/m ² with WC ≥ 90 cm in men

Elevated WC in women with a non-Asian background is ≥ 35 inches and in men with a non-Asian background is ≥ 40 inches. Elevated WC in women with an Asian background is ≥ 31.5 inches and in men with an Asian background is ≥ 35.5 inches. WC, waist circumference; WHtR, waist-to-height ratio.

*The BMI and WC thresholds identified for people with Asian backgrounds represent general targets, and health care professionals should be aware that specific values may exist for certain Asian countries that differ from the values listed above (40, 41, 55). Asian background includes Asia (e.g., China, Japan, Korea) and the South Asian subcontinent (e.g., India, Pakistan, Bangladesh). Clinicians should be aware of the evidence gap regarding individuals who identify as having mixed race or ethnicity. At this time, clinicians should use the background from which the individual identifies.

Weight Loss in People with Obesity

* Not head to head trials. Between trial comparisons should be interpreted carefully.

Preventing diabetes: Orlistat (XENDOS)

- The XENDOS study was a 4-year, double-blind, randomized, placebo-controlled, prospective study involving 3305 obese patients who were randomly assigned to receive either placebo plus lifestyle modification or orlistat at a dose of 120 mg three times daily plus lifestyle modification
- With orlistat, the incidence of diabetes decreased from 9% to 6.2%, with a 37.3% relative risk reduction

Orlistat reduces diabetes incidence in obese patients

Diabetes prevention: liraglutide 3.0 mg (SCALE Obesity and Prediabetes study)

Normalization of blood glucose: semaglutide 2.4mg(STEP 10)

- The STEP 10 study was a multicenter, randomized, controlled trial testing the effect of semaglutide 2.4mg, as compared with placebo, on a composite end point of weight and glucose reversion to normal in persons with obesity and prediabetes. The follow-up time was 52 weeks, and the observation period was 28 weeks after treatment discontinuation

The proportion of participants who returned to normal glucose levels between baseline and weeks 52 and 80 (estimated with the use of treatment strategies) during the trial observation period. Return to normal glucose levels was defined as an HbA 1c of less than 6.0% (<42 mmol/mol) and an FPG of less than 5.5 mmol/L.
Odds ratio (OR); CI, confidence interval; FPG, fasting plasma glucose; HbA 1c, glycosylated hemoglobin; N, number of subjects T2D, type 2 diabetes mellitus.
From Figure 3A+B: Proportion of participants who returned to normoglycemia or progressed to T2D in the semaglutide 2.4mg group compared with the placebo group (full analysis set)

Weight Reduction and Diabetes remission from DiRECT trial

Steatohepatitis resolution and improvement in liver fibrosis

Proportion of patients at Week 72 (full analysis set)

Significantly more patients with MASH F2–F3 treated with semaglutide 2.4 mg achieved **both primary endpoints of MASH resolution (62.9%) and improvement in liver fibrosis (37.0%)** than those treated with placebo (**34.1%, 22.5% respectively**)

Analysis set: FAS (interim), first 800 randomised subjects. EDP: Estimated difference in responder proportions with 95% confidence interval and two-sided p-value. *Resolution of steatohepatitis is defined as a NAS of 0-1 for inflammation, 0 for ballooning and any value for steatosis according to NASH CRN. No worsening of liver fibrosis is defined as no increase in fibrosis score. Fibrosis is graded on the NASH CRN fibrosis scale from 0-4. †Improvement in fibrosis is defined as ≥ 1 grade improvement on the NASH CRN fibrosis scale. No worsening of steatohepatitis is defined as no increase from baseline in NAS score for ballooning, inflammation or steatosis. The absolute difference between responder proportions, 95% confidence interval, P value was generated with the use of Cochran-Mantel-Haenszel (CMH) test stratified by baseline diabetes status (medical history) and fibrosis stage (eligibility read). ‡Missing data were handled by reference-based multiple imputation and Rubin's rule based on the Mantel-Haenszel estimator and Sato's estimate of the standard error (reference) were used to aggregate results. CI, confidence interval; EDP, estimated difference in responder proportions; F, fibrosis stage; MASH, metabolic dysfunction associated steatohepatitis; NASH CRN, Non-Alcoholic Steatohepatitis Clinical Research Network. Newsome PN et al. Oral Presentation at American Association for the Study of the Liver The Liver Meeting; Late Breaker 5018; November 19 2024; San Diego, USA.

The ADA's latest treatment recommendations for obese individuals

- Behavioral counseling
- Healthy nutritional pattern
- Aerobic and muscle-strengthening activities
- Self-monitoring
- Avoid weight-promoting medications when possible

Follow up monthly for first 3 months to monitor and modify treatment, then every 3 months for first year.
Continue long-term follow-up every 3–6 months.

Goal: achievement and maintenance of weight reduction and prevention of obesity-related diseases and complications

Weight-reducing effect of obesity medication beyond 3% weight loss with lifestyle change alone*

Without related diseases or complications

High (>10%)
Tirzepatide (A)
Semaglutide (A)

Moderate (5–10%)
Phentermine-topiramate (A)

Modest (<5%)
Naltrexone-bupropion (A)
Liraglutide (A)
Phentermine (C)+
Orlistat (A)

Select obesity medication that aligns with individual goals and does not present barriers to its long-term use‡

In the case of **inadequate treatment response** to current obesity medication, consider treatment intensification:

- Increase dose of current medication to maximally tolerated dose that does not exceed maximum approved dose
- Use an alternative obesity medication
- Combine the obesity medication with intensive behavioral therapy or structured lifestyle program
- Add another obesity medication to the current medication
- Continue obesity medication and refer for metabolic-bariatric surgery

- Behavioral counseling
- Healthy nutritional pattern
- Aerobic and muscle-strengthening activities
- Self-monitoring
- Avoid weight-promoting medications when possible

Follow up monthly for first 3 months to monitor and modify treatment, then every 3 months for first year.
Continue long-term follow-up every 3–6 months.

Goal: improvement in obesity-related diseases and complications* and accounting for achievement and maintenance of weight reduction

In the case of **inadequate treatment response** to current obesity medication, consider treatment intensification:

- Increase dose of current medication to maximally tolerated dose that does not exceed maximum approved dose
- Use an alternative obesity medication
- Combine the obesity medication with intensive behavioral therapy or structured lifestyle program
- Add another obesity medication to the current medication
- Continue obesity medication and refer for metabolic-bariatric surgery

"Disease modification" has emerged as a direction in the management of metabolic diseases

Comment

Disease modifying therapies in diabetes and endocrinology

We are living in exciting times regarding therapies for people with diabetes. Much of the excitement, for both type 1 and type 2 diabetes, is about disease modification and claims of drugs being disease modifying. But what does disease modifying mean?

One could argue that a disease-modifying therapy is an intervention that alters the course of the disease itself. The best example might be teplizumab in people with early-stage, presymptomatic type 1 diabetes; a course of 14 days of intravenous treatment with this immune-modulatory agent, which targets CD3-carrying T lymphocytes, can delay progression to insulin-requiring stage 3 type 1 diabetes by almost 3 years.¹ On the basis of these data, teplizumab was the first therapy approved for delaying progression to stage 3 type 1 diabetes in people aged 8 years or older who have stage 2 type 1 diabetes, and was also assessed in children and adolescents with new-onset, symptomatic, stage 2 type 1 diabetes. Two courses of 14-day infusions

evaluate these agents as rapidly as possible in people with type 1 diabetes. Networks such as TrialNet in the USA, the Australasian Type 1 Diabetes Immunotherapy Collaborative in Australia, and INNODIA in Europe can help to bring novel therapies to the clinic. Collaborative networks of accredited and specialised clinical trial centres can recruit people into trials and execute these trials quickly and expertly, but there is also a need to generate novel trial designs (eg, combinations of treatments and adaptive trial designs) to accelerate the process.

By contrast to type 1 diabetes, disease modification can be claimed by all incretin-based therapies in type 2 diabetes. These drugs reduce overweight and obesity and help to prevent the disease, particularly in people in presymptomatic stages. For example, the STEP⁵ and SURMOUNT⁶ programmes with semaglutide, a GLP-1 receptor agonist, and tirzepatide, a combined GLP-1 and
